

MCP, APIs & AI integrations

A working, documented connection between
your agent or application and the required
system.

Service overview / Scope / Delivery / Ownership

fortitudo.agency

What your business needs.

Install existing MCP connections, create custom MCP servers and APIs, and connect AI workflows to the applications and data they need.

Who this is for

For a missing integration, a private business tool that needs an agent interface, or a product that needs its own API.

What we deliver.

A working, documented connection between your agent or application and the required system.

01 The agreed MCP integration, custom server or API

02 Authentication, permissions and documented tool contracts

03 Data mapping, error handling and integration tests

04 Deployment guidance and source/configuration handover

The work, in detail.

MCP installation and integration

Configure an existing supported MCP server, connect it to the intended client and verify the tools against real permitted tasks.

Custom MCP creation

Expose your business systems through purpose-built tools. Define inputs, outputs, authentication and the actions each agent is allowed to perform.

The work, in detail.

Custom API creation

Build endpoints for your product or business workflow, including validation, authorization, data handling and documentation.

AI tools inside applications

Connect model and agent capabilities to product accounts, interfaces and existing workflows. Define how results are returned and failures reach the user.

A scope built around you.

MCP integration

Connect and verify an existing supported server.

Custom MCP server

Create a tool interface for your private system.

Custom API

Build and document application endpoints.

AI tool integration

Connect an agent or model to a product workflow.

From brief to handover.

- 01 Define the systems, actions and data to connect.
- 02 Agree contracts, authentication and permissions.
- 03 Implement and deploy the interface.
- 04 Test permitted actions, denied access and failure behavior.

How we assess the work.

The intended client can complete the agreed operations.

Unauthorized requests and invalid inputs are handled correctly.

The owner receives usable interface documentation and deployment details.

What shapes the proposal.

Systems and endpoint count

Authentication and data mapping

Deployment and operational
requirements

Third-party API access, limits and fees depend on the provider. The proposal identifies supported operations and maintenance responsibility.

Price, timing and responsibilities are agreed in the proposal. Third-party fees and ongoing support are identified separately.

A clear start. Practical ownership.

What we need from you

System documentation, authorized accounts, sample data and access requirements.

What happens next

Show us the systems you need to connect and the actions you want to expose.
